FREQUENCY COMPENSATION SCHEME FOR LOW DROP OUT VOLTAGE REGULATORS USING ADAPTIVE BIAS

5

Technical field of the Invention

This invention relates generally to voltage regulators, and more particularly to an enhancement of low dropout voltage regulators having an adaptive biased driving stage in order to improve stability through a very wide range of output current.

10

Background art

15

Low-dropout (LDO) linear regulators are commonly used to provide power to low-voltage digital and analog circuits, where point-of-load and line regulation is important. Fig. 1 prior art shows a typical basic circuit of a LDO regulator 3 having an input voltage V_i 1, an output voltage V_o 2, an input current I_i and an output current I_o .

20

Conventional LDO regulators are very problematic in the area of transient response. Transient response is the behavioral of the regulator after a abrupt change of either the load current (load response) or the input voltage (line response). A minimum under and overshoot of the regulated voltage and a fast settling is desired. The transient response is defined by the frequency compensation of the regulation loop. Voltage regulators are difficult to compensate because of the fact that the load resistance and with this the output pole can vary over a wide range. For zero load the load resistance is infinite and the output pole is zero Hz. For maximum load the load resistance is at its minimum and the output pole is as its maximum, that might be a few KHz.

30

Said frequency compensation is still a challenge for the designers of LDO regulators

U. S. Patent (6,246,221 to Xi.) describes a high power supply ripple rejection (PSRR) internally compensated low drop-out (LDO) voltage regulator using an output PMOS pass device. The voltage regulator uses a non-inversion variable gain amplifier stage to adjust its gain in response to a load current passing through the output PMOS device such that as the load current decreases, the gain increases, wherein a second pole associated with the voltage regulator is pushed above a unity gain frequency associated with the voltage regulator.

Fig. 2 prior art shows a simplified circuit of an embodiment of a PMOS LDO according to said U.S. Patent 6,246,221 to Xi. Said regulator is a multiple-loop regulator. Said circuit comprises a gm-buffer amplifier **202** to push the gate pole of the PMOS pass device **201** to high frequencies. Transistor **203** serves for adaptive biasing the gm-buffer amplifier **202**. **211** represents the equivalent series resistance (ESR) of the load capacitor **213**. **212** represents the equivalent series inductance (ESL) of the load capacitor **213**. In case of low loads the out-pole formed by the load capacitor **213** and the load resistance **210** goes to low frequencies and thus it is possible to lower the gate-pole also.

In the non published European patent application n° EP-A- 03 392 001.8 filed on January 16th 2003 , entitled REGULATED CASCODE STRUCTURE FOR VOLTAGE REGULATORS and assigned to the Assignee of the present European patent application, a LDO is described having an error amplifier as part of a current mirror output stage. A method and a circuit to achieve a low dropout voltage regulator having a constant high performance under all operating conditions, including the dropout region, has been disclosed in said patent application. A regulated cascode structure is placed at the input of a current mirror and in connection with a voltage regulator output stage. In contrast to other applications the positive input of the error amplifier is not biased with a reference voltage but connected to the regulator output. Therefore the cascode structure regulates the voltage of the entry node of the current mirror to be equal to the

output voltage of the regulator under all operating conditions of the regulator. Thus the transistors of the current mirror have always identical drain-source voltages. Therefore the regulator is kept in the optimal, balanced operating point, a constant high regulator loop gain is achieved and PSRR and load regulation
5 performance is no more reduced under dropout operating conditions.

Fig. 3 prior art shows a simplified circuit of an embodiment of a LDO according to the above mentioned non published European application **302** is the input transistor of a current mirror formed by PMOS pass device **301** and said input transistor **302**. Equivalent to **Fig. 2 prior art 311** represents the equivalent
10 series resistance (ESR) of the filter capacitor **313**. **312** represents again the equivalent series inductance (ESL) of the filter capacitor **313**. **310** represents the load resistance of said LDO again. In said embodiment the gate-pole of the PMOS pass device **301** moves in a constant ratio with the out-pole. Said gate-pole of the pass device is formed by the gate capacity C_{gate} of transistor **301** and
15 $1/gm$ of the input transistor **302**, wherein gm represents the transconductance gain of transistor **302**. Said out-pole is formed by the load resistance **310** and the load capacitor **313**.

There are additional patents dealing with the stabilization of LDOs.

U. S. Patent Application Publication 2002/0130646 (to Zadeh et al.)
20 describes a linear voltage regulator, such as a low-dropout regulator, supplying power to one or more digital circuits within a computer system. The low-dropout regulator provides a substantially constant output voltage independent of loading conditions. The low-dropout regulator is biased at a relatively low operating current for steady-state operation to improve power efficiency of the low-dropout
25 regulator. During a loading condition change, an adaptive biasing circuit senses the loading condition change and provides additional biasing current to momentarily increase the operating current of the low-dropout regulator to improve transient response.

Summary of the invention

A principal object of the present invention is to improve the stability of low
5 dropout voltage regulators (LDO) having an adaptive biased driving stage.

A further object of the present invention is to keep the current consumption
of said LDOs at a minimum.

10

In accordance with the objects of this invention a circuit to improve the
stability of a low drop-out (LDO) voltage regulator has been achieved. Said circuit
comprises a means of an adaptive biased driving stage of said LDO, an
impedance being connected on one side to said means of an adaptive biased
15 driving stage and on the other side to the gate of a pass device of said LDO, a
pass device of said LDO, wherein its gate is connected to said impedance and the
source and drain are connected to V_{DD} voltage and to the output voltage of said
LDO, and a filter capacitor being connected to ground and to the output voltage of
said LDO.

20

In accordance with the objects of the invention a method to improve the
stability of a low drop-out (LDO) voltage regulator has been achieved. Said
method comprises first providing a pass device for an adaptive biased driving
25 stage. The steps of the method invented are to add a serial impedance to the gate
capacitance of said pass device and to shunt partly said impedance in case of
medium load currents as far as required.

30

Description of the drawings

5 In the accompanying drawings forming a material part of this description,
there is shown:

Fig. 1 prior art illustrates the principal currents of an LDO.

10 Fig. 2 prior art shows a LDO using a gm-buffer amplifier

Fig. 3 prior art shows a LDO using a current mirror.

15 Fig. 4 shows an embodiment of the present invention with an LDO
using a gm-buffer amplifier as driving stage.

Fig. 5 shows another embodiment of the present invention with an
LDO using a gm-buffer amplifier as driving stage.

20 Fig. 6 shows an embodiment of the present invention with an LDO
using a current mirror as driving stage.

Fig. 7 shows a schematic of a circuitry to perform shunting of an
impedance in two steps in case of medium load currents.

25 Fig. 8 shows a flowchart of a method to improve the stability of
LDOs, having an adaptive biased driving stage

30

Description of the preferred embodiments

The preferred embodiments disclose circuits and a method for
5 enhancements of low drop-out (LDO) voltage regulators having adaptive biased
driving stages in order to improve the stability of the regulation loop of said LDOs.
Said embodiments of the present invention can be used e.g. in multiple loop
regulators as disclosed in U.S. 6,246,221 and described in the prior art section of
this application or can be used e.g. with LDOs using current mirrors.

10 In order to achieve stability of the regulation loop of said LDOs it is
necessary that the gate pole, formed by the inner resistance of the driving stage
and the gate capacitance of the PMOS pass device, is at least N times higher
than the output pole formed by load resistance and the load capacitance.

15 N has to be equal or higher than the open-loop gain of the LDO. For
example, if the open-loop gain is 60 dB, i.e. 1000, then N has to be higher than
1000. This statement is only valid as long the inductances can be neglected.
Usually LDO circuits use capacitors having a capacitance in the order of
20 magnitude of 1 – 3 μ F. Said capacitors may have a serial inductance of about
1nH. The PCB routing, the chip package and the bonding wires of the package
may also have 1 – 20 nH inductance. Therefore the resonance frequency of the
out “tank” is in the order of magnitude of 500 KHz to 3 MHz. For an adaptive
biased gm-buffer, as described in Fig. 2 prior art, or an input of a current mirror,
25 as described in Fig. 3 prior art, the LDO gets instable for high currents as
explained below.

The problem of said prior art solutions is that for low loads and resulting
low output poles the gate pole must be N times higher than the output pole. There
30 is no impact of the serial inductance. For high currents the output pole goes up. In
case the gate pole goes up in the same way (keeping the ratio of gate and output
pole constant) the gate pole gets much higher than the resonance frequency of
the output “tank”. Above the resonance frequency the impedance of the output

"tank" rises again and the phase shifts by 180 degrees. Thus the regulator gets unstable.

As a key point of the present invention the moving gate pole, formed by the inner resistance of the adaptive biased driving stage and the gate capacitance of the PMOS pass device, is kept close to the resonance frequency for high load currents. It should be noted that a second, fixed pole close to the resonance frequency of the output "tank" is necessary to ensure regulation loop stability. This pole is usually formed at the output of the error amplifier (not shown here). **Fig. 4** shows a preferred embodiment of the present invention. It shows a circuit of an LDO using an adaptive biased gm-buffer, similar to the circuit described in **Fig. 2** prior art. In the circuit shown in **Fig. 4** a gm-buffer **402** pushes the gate pole of the pass device **401** to high frequencies. Transistor **403** provides adaptive biasing of the gm-buffer **402**. Resistor **411** represents the equivalent series resistance (ESR) of the filter capacitor **413**. Inductor **412** represents the equivalent series inductance (ESL) of the filter capacitor **413**. In case of low loads the output-pole formed by the load **410** and the capacitance **413** goes to low frequencies and it is therefore possible to lower the gate pole.

Said preferred embodiment shown in **Fig. 4** is thus characterized that a serial resistor **420** is added to the gate capacitance. In said preferred embodiment of the present invention a resistor has been selected. Another kind of impedance, e.g. a transistor, besides a resistor could have been used as well. In case of low load the resistance of said resistor **420** is not dominating, in case of high load said resistance keeps the gate pole close to the resonance frequency of the output "tank", formed by the capacitor **413** and the equivalent series inductance (ESL) of the filter capacitor **413**. Said resonance frequency f_r is defined by the equation

$$f_r = \frac{1}{2 \times \pi \times \sqrt{L \times C}},$$

wherein L represents the equivalent series inductance (ESL) **412** and C represents the capacitance of the capacitor **413**.

Fig. 5 shows another embodiment of the present invention: Said circuit shown in **Fig. 5** is similar to the circuit shown in **Fig. 4**. **Fig. 5** shows again a circuit of an LDO using an adaptive biased gm-buffer, similar to the circuit described in **Fig. 2 prior art**. In the circuit shown in **Fig. 5** a gm-buffer **502** pushes the gate pole of the pass device **501** to high frequencies. Transistor **503** provides adaptive biasing of the gm-buffer **502**. Resistor **511** represents the equivalent series resistance (ESR) of the filter capacitor **513**. Inductor **512** represents the equivalent series inductance (ESL) of the filter capacitor **513**.

Said preferred embodiment shown in **Fig. 5** is thus characterized that a serial resistor **520** is added to the to the gate capacitance and, differentiating from the circuit shown in **Fig. 4**, the adaptive biasing transistor **503** is connected to the gate of the pass device **501** and not, as shown in **Fig. 4**, to the output of the adaptive biased gm-buffer. There is no difference in functionality between the circuit shown in **Fig. 4** and the circuit shown in **Fig. 5**.

Fig. 6 shows another embodiment of the present invention: Said circuit shown in **Fig. 6** is similar to the circuit shown in **Fig. 3 prior art**. **Fig. 6** shows also a circuit of an LDO using a current mirror. **602** is the input transistor of a current mirror formed by PMOS pass device **601** and said input transistor **602**. Resistor **611** represents the equivalent series resistance (ESR) of the filter capacitor **613**. Inductor **612** represents the equivalent series inductance (ESL) of the filter capacitor **613**. The gate pole, which is formed by the gate capacity of the pass device **601** and by the reciprocal value of the transconductance $1/g_m$ of said input transistor **602** of said current mirror, moves in a constant ratio with the output pole, which is formed by the capacity of the filter capacitor **613** and by the resistance of the load **610**.

Compared to the circuit showed in **Fig. 3 prior art** said preferred embodiment of the present invention shown in **Fig. 6** is thus characterized that a serial resistor **620** is added to the gate capacitance of said pass device **601**. Instead of said resistor **620** another kind of impedance, e.g. a transistor, could be used as well. In case of low load the resistance of said resistor **620** is not

dominating, in case of high load said resistance keeps the gate pole close to the resonance frequency of the output "tank", formed by the capacitor **613** and the equivalent series inductance (ESL) of the filter capacitor **613**. As described above said resonance frequency is defined by the equivalent series inductance (ESL)
5 **612** and by the capacitance of the capacitor **613**.

Summarizing the characteristics of the embodiments of the present invention shown in **Fig. 4 - 6** it should be understood that the resistance of the serial resistor **420** respective **520** or **620** is during low load conditions, i.e. low
10 frequencies, small compared to the inner resistance of the gm-buffer **402** respective **502** or the inner resistance input of the current mirror shown in **Fig. 6**.

With an increase of the load current the inner resistance of the driving stage falls, it keeps the ratio of gate pole to output pole constant. Said ratio has
15 been denominated with "N" above. For a high load the serial resistor dominates and keeps the gate pole close to the resonance frequency of the output "tank", even if the inner resistance of the driving stage goes to zero.

A problem may arise for medium load currents where the inner resistance
20 of the driving stage equals the resistance of the serial resistor **420** respectively **520** or **620**. In this case the gate pole could be too low. A possible solution of said problem could be to increase the ratio N of the gate pole to the output pole but this has the disadvantage of a higher current consumption.

Fig. 7 shows another embodiment of the present invention solving the
25 problem of medium loads. V_{IN} represents the input voltage of an adaptive biased driving stage, e.g. a gm-buffer or the gate voltage of an input transistor of a current mirror, and V_{OUT} represents the output voltage of the LDO shown. Equivalent to **Fig. 2-6** resistor **711** represents the equivalent series resistance
30 (ESR) of the filter capacitor **713**. **712** represents the equivalent series inductance (ESL) of the filter capacitor **713**. **710** represents the load resistance of said LDO. For medium and small loads the serial resistor **720** will be shunted by PMOS switches **742** and **741**, saving current consumption of the driver stage **701**. The

amount of shunting will be defined by the on-resistance of said PMOS switches **742** and **741** or additionally by optional resistors **781** and **782**. Transistors **761** and **762** are level shifters. Transistor **750** generates the gate voltage for the transistors **751** and **752**.

5

Transistors **731** and **732** generate currents in a fixed ratio to the output current. In case

$$I_{731} < I_{770} \times \frac{L_{750}}{W_{750}} \times \frac{W_{751}}{L_{751}},$$

wherein I_{731} is the current flowing through transistor **731**, I_{770} is the current provided by the current source **770**, L_{750} is the gate length of transistor **750**, W_{750} is the gate width of transistor **750**, L_{751} is the gate length of transistor **751**, and W_{751} is the gate width of transistor **751**, then the gate potential of transistor **741** goes to zero and said transistor **741**, acting as a switch, shunts resistor **720**.

15 In the embodiment of the present invention shown in Fig. 7 the resistor **720** is shunted in two steps. In case

$$I_{732} < I_{770} \times \frac{L_{750}}{W_{750}} \times \frac{W_{752}}{L_{752}},$$

wherein I_{732} is the current flowing through transistor **732**, I_{770} is the current provided by the current source **770**, L_{750} is the gate length of transistor **750**, W_{750} is the gate width of transistor **750**, L_{752} is the gate length of transistor **752**, and W_{752} is the gate width of transistor **752**, then the gate potential of transistor **742** goes to zero and said transistor **742**, acting as a switch, shunts resistor **720** as well. Using different resistance values for the resistors **782** and **781** the total serial gate resistance of the PMOS pass device **701** can be tuned according to the requirements. Thus the serial resistor **720** can be shunted stepwise for different load currents having a medium load order of magnitude. By reducing as described, the gate resistance of the PMOS pass device **701** in case of medium load currents the gate pole can be thus held on the optimum frequency. The ratio N can be reduced as far as possible. Thus the current consumption of the driving stage can be kept to a minimum.

It should be understood that the shunting of the serial gate resistor can be performed by one step only or by more than one step. Shunting in two steps has been shown in **Fig. 7** and has been explained above. In case shunting in one step
5 is desired then transistors **732, 752, 742** and the resistor **782** are not required. In case three steps of shunting are desired additional transistors can be deployed in parallel to transistors **732, 752** and **742** and a additional resistor can be deployed in the same way as resistors **781** and **782**. It is obvious that more than three steps of shunting can be introduced also by adding correspondent additional transistors
10 and resistors.

Fig. 8 shows the basic steps of a method to increase the stability of an LDO comprising a pass device. The first step **81**, as described above, comprises to add a serial impedance to the gate capacitance of said pass device. The next
15 step **82** comprises to shunt said impedance partly as far as required in case of medium load currents.

While the invention has been particularly shown and described with
20 reference to the preferred embodiments thereof, it will be understood by those skilled in the art that various changes in form and details may be made without departing from the spirit and scope of the invention.

Claims

- 1.A circuit to improve the stability of a low drop-out (LDO) voltage regulator
5 comprising:
- a means of an adaptive biased driving stage of said LDO;
 - an impedance being connected on one side to said means of an adaptive biased driving stage and on the other side to the gate of a pass device of said LDO;
 - a pass device of said LDO, wherein its gate is connected to said impedance and
10 the source and drain are connected to VDD voltage and to the output voltage of said LDO; and
 - a filter capacitor being connected to ground and to the output voltage of said LDO.
- 15 2. The circuit of claim 1 wherein said impedance is a resistor.
3. The circuit of claim 1 wherein said impedance is provided by a transistor.
4. The circuit of claim 1 wherein said impedance can be reduced during specific
20 load conditions using an additional parallel impedance.
5. The circuit of claim 4 wherein said specific load condition is a medium load condition.
- 25 6. The circuit of claim 4 wherein said parallel impedance is a transistor.
7. The circuit of claim 4 wherein said parallel impedance is a transistor having a serial resistor.
- 30 8. The circuit of claim 4 wherein said reduction of said impedance is performed in more than one step depending on the size of the load current.

9. The circuit of claim 8 wherein said reduction of impedance is performed by adding in each step an additional parallel impedance to the first impedance.
10. The circuit of claim 9 wherein said additional parallel impedances are formed
5 by parallel arranged transistors.
11. The circuit of claim 8 wherein said additional parallel impedances are formed by parallel arranged transistors having a serial resistor.
- 10 12. The circuit of claim 4 wherein a special circuitry detects said specific load conditions and initiates said reduction of the impedance connected to the gate of said pass device depending on the size of the load current of said LDO.
- 15 13. The circuit of claim 12 wherein said specific load condition is a medium load current.
14. The circuit of claim 12, detecting a specific load condition and initiating a reduction of the gate impedance of said pass device in one step, wherein said special circuitry comprises a current source connected to ground and to a first
20 transistor, which is connected via two additional transistors, acting as level shifters to V_{DD} voltage and furthermore the gate of said first transistor is connected to said current source and to the gate of a second transistor, which is connected to ground and to a third transistor, which is connected to V_{DD} , and to the gate of said transistor, being a shunt to the impedance to be reduced, and wherein the gate of
25 said third transistor is connected to the impedance to be reduced.
15. The circuit of claim 12, detecting a specific load condition and initiating a reduction of the gate impedance of said pass device in more than one step, wherein said special circuitry comprises a current source connected to ground
30 and to a first transistor, which is connected via two additional transistors, acting as level shifters to V_{DD} voltage and furthermore the gate of said first transistor is connected to said current source and to the gate of a second transistor, which is connected to ground and to a third transistor, which is connected to V_{DD} , and to

the gate of said transistor, being a shunt to the impedance to be reduced, and wherein the gate of said third transistor is connected to the impedance to be reduced, and wherein for each additional step of impedance reduction two additional transistors in parallel to said second and third transistors are introduced, which are controlling the gate of one for each step additional transistor which is an additional shunt to the impedance to be reduced.

16. A method to improve the stability of a low drop-out (LDO) voltage regulator comprising:
- providing a pass device for an adaptive biased driving stage;
 - add a serial impedance to the gate capacitance of said pass device; and
 - shunt partly said impedance in case of medium load currents as far as required.

17. The method of claim 16 wherein said adaptive biased driving stage is a gm-buffer.

18. The method of claim 16 wherein said adaptive biased driving stage is a current mirror.

19. The method of claim 14 wherein said serial impedance is a transistor.

20. The method of claim 14 wherein said serial impedance is a resistor.

21. The method of claim 14 wherein said serial impedance is shunted by a transistor.

22. The method of claim 14 wherein said serial impedance is shunted by a transistor having a serial resistor.

23. The method of claim 14 wherein said serial impedance is shunted in more than one step.

ABSTRACT

A method and circuits to improve the stability of low dropout voltage regulators having an adaptive biased driving stage. Said improvement of stabilization is valid through the total range of output current possible. A serial impedance is added to the gate capacitance of the PMOS pass device of said LDO. Said serial impedance could be a resistor or a transistor. In case of low load currents said impedance is not dominating, for high load currents said impedance keeps the gate pole close to the resonance frequency of the output tank. In case of medium load currents, wherein the inner resistance of the driving stage is about equal to said serial impedance, the gate pole could get too low. This problem is solved by reducing said serial impedance by shunting. Said shunting can be performed stepwise depending on the size of the load current. A special circuitry detects the condition of medium load currents and can initialize the shunting of said serial impedance accordingly in order to keep the gate pole on the optimum frequency.
